#Email Slicer

To make an email slicer in Python, we'll need to construct a program that can obtain the email's username and domain name.

As a result, we must split the email into two strings using the '@' separator. Let's look at how to use Python to separate the email and domain name:

```
[1]: #code
```

```
[27]: #input the mail
email=input("Enter the mail:")
username=email[:email.index('@')]
domain=email[email.index('@')+1:]
```

Enter the mail:52chandrasekar@gmail.com

```
[32]: # printing result
print("Your user name is :",username," and your domain: ",domain)
```

Your user name is : 52chandrasekar and your domain: gmail.com
